India Country Profile - Netzero Steel Project

The Netzero Steel Project considers the geo-spatial evolution of production of 22 existing facilities in India described in the GEM database that account for 73% of India’s 2019 production, as well as 32 smaller additional archetype plants that were added to account for missing production. All scenarios achieve >90% reduction in emissions by 2050, see the full report for the methodology and background to the study.

All the nine modelled scenarios (3 demand scenarios) and (3 CCS pipeline length scenarios) reduce overall emission intensities from an estimated existing emission intensity of 1.52 tCO2e/tonne of steel in 2019 to 0.13 tCO2e/tonne of steel in 2050. This compares to a global average of 1.58 in 2019 and 0.14 tCO2e/tonne of steel in 2050. Note that the study boundary includes all direct energy and process emissions that occur at integrated iron and steel mills, but does not include GHG Protocol Scope 2 or Scope 3 class emissions that occur off-site, or allow for the crediting of exported energy products (See report for more details).

**Demand Transition**

- In the medium demand scenarios India’s steel demand increases 205% between 2020 and 2050.
- low/medium/high scenarios in 2050 correspond to 190/224/258 tonnes crude steel per capita. This compares to a global average of 206/236/267 tonnes crude steel per capita.
- Secondary production from scrap in EAF rises from 23% in 2020 to 36% in 2050 in our central scenario. This compares to the projected global average of 46%.

**Technology Transition**

- By 2034 more than half of India’s production is projected to be low carbon in the central scenario.
- DRI-EAF-H2 rises in market share from zero in 2027 to 52% in 2050 in our central scenario (range of scenarios is 48% to 68%).
- Steel production with CCS retrofit accounts for 11% of production in the 2050 central scenario (range of scenarios is 0% to 18%).
- Green imports or non spatially allocated production accounts for 2% of production in the 2050 central scenario (range of scenarios is 1% to 3%).

**Energy Transition**

- Facility energy demand for fossil fuels falls by 55% by 2050 in the central scenario (range of scenarios is 16% to 96%).
- Electricity demand rises to 748 TWh in 2050, a rise from current levels of 11.8x by 2050 in the central scenario (range of scenarios is 9.9x to 15.8x). For comparison, electricity demand in 2050 represents 47% of current total electricity demand in India.
- Electricity demand for hydrogen rises to 530 TWh by 2050 in the central scenario (range of scenarios is 418 to 800 TWh).
India Country Profile - Netzero Steel Project

**Investment Transition**

- CAPEX investment increases by 397% from 2020 to 2050 in the central scenario.
- DRI-EAF-H2 contributes to the largest share of CAPEX investment, 70% in 2050 in the central scenario.

- Total production costs in 2020 $USD are estimated to be $78 billion in 2030 and $177 billion in 2050 for the central scenario.
- CAPEX costs are projected to be 16% of overall production costs in 2050 for the central scenario.

**Emissions Transition**

- Cumulative emissions between 2030 and 2050 are 3,764 MtCO2e (Range for scenarios is 3,608 to 3,927 MtCO2e.)
- Emission intensity of production falls from 1.51 tCO2e/tonne of crude steel in 2020 to 0.13 tCO2e/tonne of crude steel in 2050.
